Intelligent Stepper Motor Controllers

User Instructions Rev 642

Introduction

The **ICST02** Intelligent Stepper Controller provides the means to control all of Fluid Metering's pumps including the FENYX, FDD, STF, and STFQ. By properly configuring Fluid Metering's ICST02 controller one can increase the performance efficiency of a connected pump over a wide range of speeds. This document will describe the individual connections on the controller, their electrical specifications, and their functions. For mechanical details refer to outline drawing 600298 Rev B.

This document will also introduce a software application "[FMI Configuration Tool](#)" that can be used to manage settings within the controller. This application will help to determine the optimal settings for the operation of the pump.

Quick Start Guide

Step 1: Prepare the Hardware

- **Power Supply:** Connect a 24VDC power supply to the controller's J6 connector.
- **Motor Connection:** Attach the motor to the J8 connector (A+/A-, B+/B-).
- **Other Connections:** Ensure all additional necessary connections (e.g., RS232, sensors) are secure.

Step 2: Install the FMI Configuration Tool

1. This application requires Microsoft dotnet framework 4.8 to be present. It can be downloaded and installed from:
[Download .NET Framework 4.8 | Free official downloads](#)
2. Locate the setup.exe file in the installation folder.
3. Double-click to run the installer and follow on-screen instructions.

Step 3: Connect to the Controller

1. Use an FTDI RS232-to-USB converter to connect the controller to your PC.
2. Launch the FMI Configuration Tool.
3. Select the correct COM port from the dropdown menu and click "Open Port."
4. Verify the connection is successful before proceeding.

Step 4: Configure Initial Settings

- Open the Configuration Tool's main screen.
- Load Factory Default settings for optimal performance.
- Adjust motion parameters (Speed, Strokes, etc.) if needed.

Step 5: Perform an Initial Test

1. Press **Start** in the Configuration Tool to begin motion.
2. Observe motor movement and verify proper operation.
3. Use **Stop** to halt the operation and ensure the controller responds correctly.

Overview of Functionality

I/O Connector (J10)

IN0 (J10.1): RUN/STOP - Connection to ground initiates a run.

- In Dispense mode a momentary connection is required. When momentarily connected to ground, the pump will run at a set number of revolutions based on the voltage reading on analog input IN4 (VDISP). **Table 1** is provided as a reference that maps voltages to stroke counts.
- The number of revolutions can also be stored into the controller using the FMI Configuration Tool when IN4 is tied to ground.
- In continuous mode a connection to ground will keep the pump running. Removing the connection to ground stops the pump.

IN1 (J10.2): DIRECTION - When operating a rotary variable¹ dispense pump, when IN1 is connected to ground pump will move to Home Position. With other types of pumps connected to the port, Connection to ground will run the pump in reverse (motor counter-clockwise) to aspirate fluid. Leave open to run pump forward (motor clockwise) to dispense fluid.

IN2 (J10.3): DISPENSE/METER – When operating a variable² dispense actuator, when IN2 is connected to ground actuator will move to Home Position. When other types of pumps are connected to the port, connection to ground enables dispense. Leave open to enable metering (continuous flow).

IN3 (J10.4): SENSOR OUPUT – This input line uses the sensors output to home the pump on power up. The pump will home halfway on the intake. The position is direction dependent.

IN4 (VDISP) (J10.5): CYCLES – Two options are available on how to set the number of cycles the pump will rotate.

- Analog Input accept a voltage from 0 to 5 VDC. The value determines the number of cycles the pump will rotate.
- The number of cycles can also be set using the FMI Configuration Tool when IN4 is grounded.

Anode (J10.6): SENSOR ANODE – This output provides the voltage source for the LED of the sensor. It is important to connect the sensor anode here and NOT +5. Sensor anode current limiting resistor is installed on this pin to protect sensor anode from damage.

GND (J10.7): GND – Logic ground

¹ Variable Dispense firmware for Rotary motor should have an Application ID of 301273-0000-VDRP18 or newer.

² Variable Dispense firmware for Actuator motor should have an Application ID of 301273-0000-VDLP18 or newer.

+5 (J10.8): VCC – 5 VDC output 250 mA max.

V_{REF} (J10.9): SPEED (RPM) – Voltage input from 0 to 5 VDC. Speed will depend on the voltage reading on this analog input. When **V_{REF}** is tied to ground, speed will be set to the value that was stored into the controller using FMI Configuration Tool.

OUT0 (J10.10): MOTION COMPLETE – This output is “HIGH” when pump is in motion and “LOW” when pump motion is complete.

OUT1 (J10.11): ERROR – General error. “HIGH” = no error. “LOW” = error. Power down to reset.

GND (J10.12): GND – Logic ground

Table 1- Voltage applied to IN4 (VDisp) to achieve the listed number of dispenses

FMI Configuration Tool

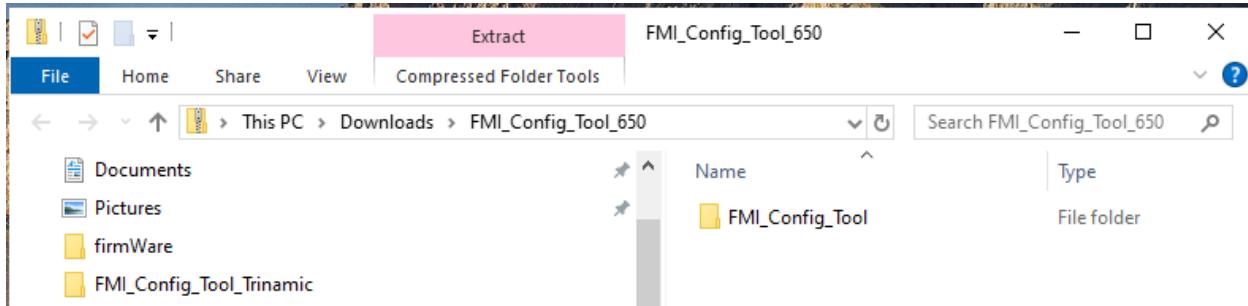

Is a windows based application that makes it possible to examine different motion settings against ICST02 controllers. It also makes it possible to save values related to desired motion parameters into an ICST02 controller. The following sections will provide the steps necessary for proper installation and operation of this application.

Installation

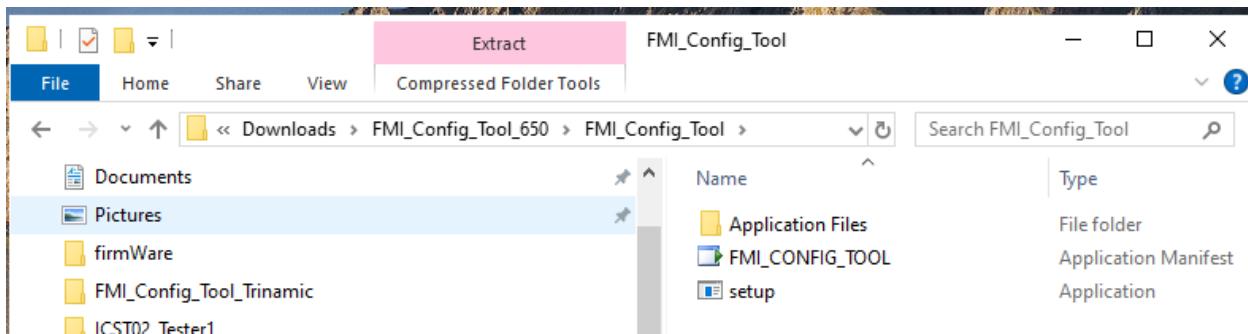

After downloading FMI Configuration Tool installation file, click on **open file** as shown below:

Next open the **FMI_Config_Tool** folder:

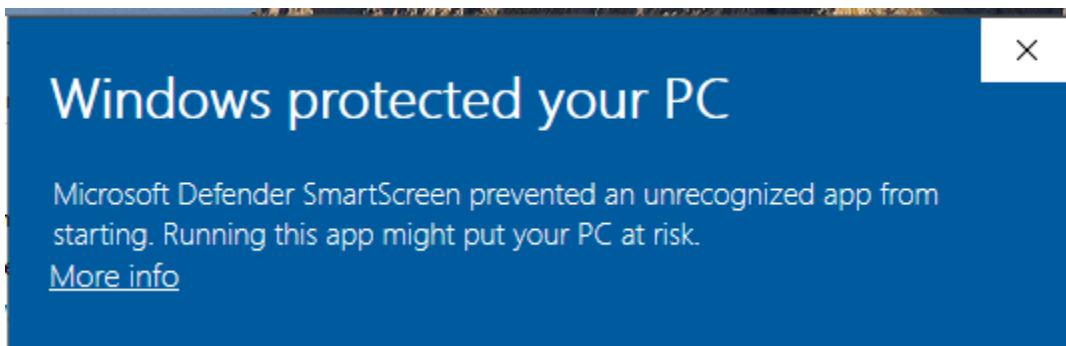

Next double click on **setup.exe**:

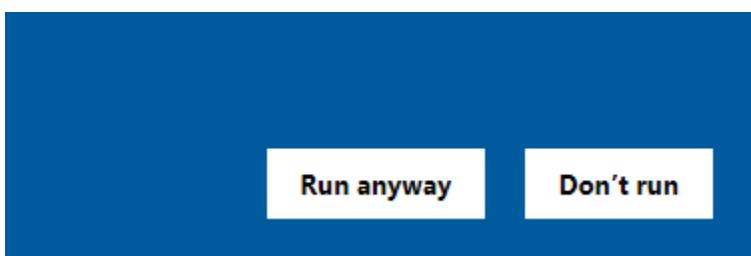

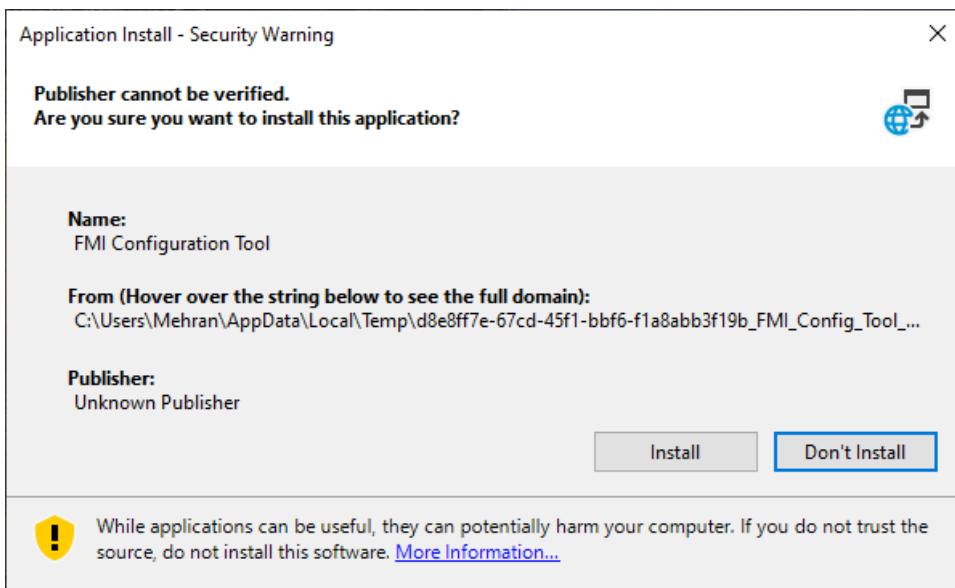

Next click on **More Info**:

Next Click on **Run anyway**:

Next, click on **Install**:

This application requires .NET Framework 4.8. It will attempt to download it if one is not already present. As soon as installation is complete, FMI Configuration tool will start, and connection screen will be displayed. You can also start the application from “Start” menu in Windows 10 or “program files” menu in Windows 7. Next section will explain all the parameters and settings

that must be in place for the FMI Configuration tool to successfully connect to an ICST02 controller.

Connecting to the Controller

First connect the FMI Configuration tool to the ICST02 controller using the USB to serial converter (**Future Technology Devices International (FTDI) US232R-10, RS232 to USB serial converter is recommended. You must download and install required windows drivers to use this USB serial converter**).

Next power on the controller using proper 24 VDC power supply. When the Configuration tool is started it will automatically scan and populate the **Ports** selection box with all the COM ports. You can use your Windows device manager to determine which one of the COM ports is associated with the ICST02 controller.

To connect to the controller, make sure **Controller** is set to ICST02, and **channel type** is set to “RS 232”, and select the desired baud rate. After selecting communication port values, click on “Open Port”. If connection fails, the application will display an error message.

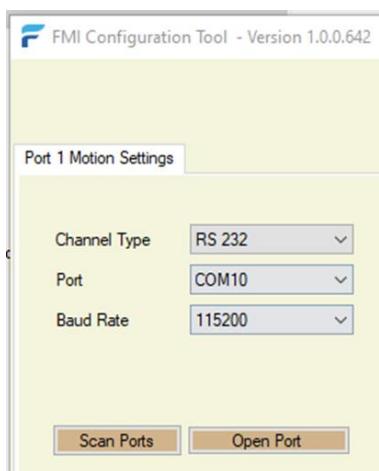

Figure 1 - Connection Dialog

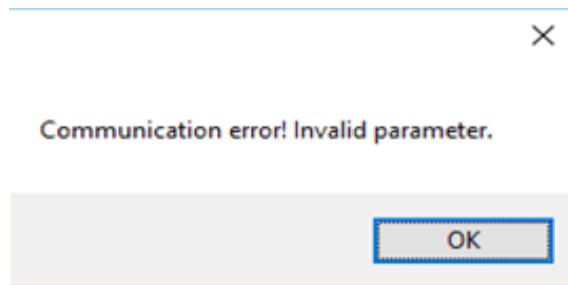

Figure 2 - Failed connection message

If connection succeeds, FMI Configuration tool will display main Configuration screen which is populated using values from its previous execution (if one is available). Communication error dialog will be displayed if incorrect COM port is used.

Following section will discuss elements that make up the Configuration screen.

Configuration Screen

Is made up of 4 main sections, **Motion Settings**, **Pump Control**, **Menu Strip**, and the **general information area** on the left.

Motion Settings

Include parameters whose values affect the motion of the pump. Motion Settings are made up of the following rows: Speed, Strokes, Acceleration, Run Current, Standby Current, Flow Direction, and Flow Method.

Each row displays values from four different sources: **Factory Default**, **User Input**, **Analog Input**, and **Controller**.

- **Factory Default:** Values that are recommended by Fluid Metering for optimal operation of the pump. These values cannot be modified.
- **User Input:** Values that are entered by user. These values can be modified by the user.
- **Analog Input:** These values are read from the ICST02 controller's input ports. As values change on the input ports, they get updated into their respective fields on the screen. These values cannot be modified by the user.
- **Controller:** Values that are currently stored in the controller. These values cannot be modified by the user.

A checkbox is displayed below each of the value fields. On any given row only one checkbox can be in checked state. When a box is checked its related value will be used to operate the pump. Value that will be used to operate the pump are highlighted in yellow to help the user to identify them visually.

FMI Configuration Tool - Version 1.0.0.642

Figure 3 – Main Configuration Screen

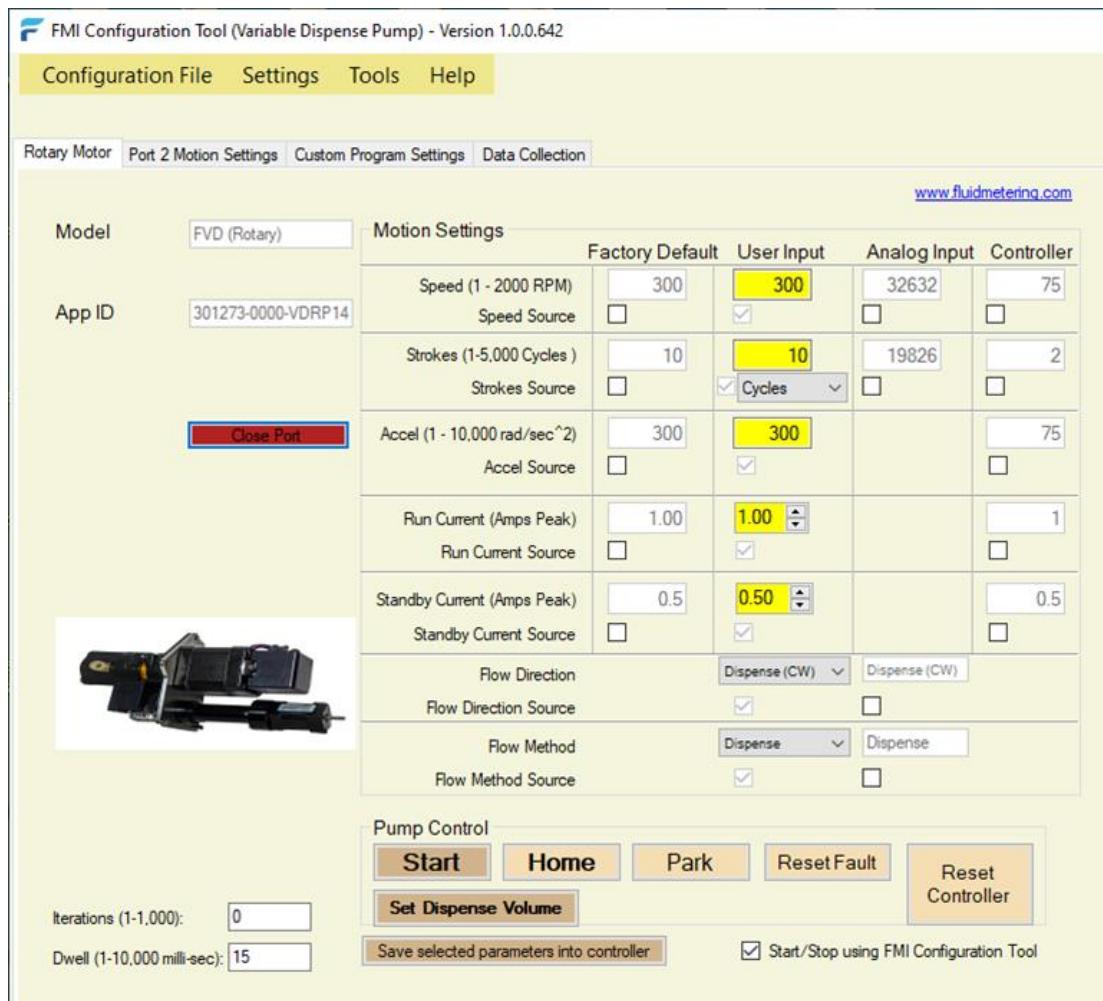

Figure 4 – Main Configuration Screen for a Variable Dispense Pump

Display of some of the parameters on the configuration screen depends on the type of controller configuration tool connects to. If configuration tool connects to a variable dispense pump controller, an extra tab will be displayed to accommodate management of the rotary motor, and, the actuator (using a Linear Motor) and also a custom program setting that will be discussed in later sections.

Following is a brief description of the Motion Parameters:

- **Speed** – Is used to vary the flow rate (flow rate based on pump calibration). Refer to Fluid Metering's calibration data sheet that shipped with the pump.
- **Strokes** – Is used to set the number of strokes (cycles, steps, or micro-steps) that pump will complete when in dispense mode.
- **Acceleration** – Sets acceleration of the motor

- **Run Current** (Amps Peak) – Is used to set the amount of current (In Amps) that the controller provides to the motor when it is running.
- **Standby Current** (Amps Peak) – Is used to set the amount of current (In Amps) that the controller provides to the motor when it is in standby mode (not rotating).
- **Flow Method** – Allows the user to toggle between continuous flow (**Meter**) or a set number of strokes (**Dispense**). When Meter is selected, all parameters related to Strokes will disappear. Value of Flow Method displayed in the **Analog Input** column is read only and represents the value that is read from respective ICST02 controller's input port.
- **Flow Direction** – Allows the user to set the direction that the pump will rotate in. Flow Direction displayed in the **Analog Input** column is read only and represents the value that is read from respective ICST02 controller's input port.

Pump Control

Elements in Pump Control group are used to send motion or administrative commands to the controller. Following is a brief description of each of these commands:

- **Start** – This command instructs the controller to move the pump using selected motion parameters. When pump starts its movement, only parameters that influence its motion will be displayed in the Motion Settings area.
- **Stop** – This command instructs the controller to stop the pump from moving. After pump comes to complete stop, all Motion Parameters will be displayed, and user input will be accepted.
- **Home** – This command moves the pump to its “Home” position (A position where the flat of the piston is facing the inlet port).
- **Park** – This command moves the pump to its Parked position where Piston will be nearest to the bottom (smallest gap) "TDC" - Top Dead Center
- **Reset Controller** – Resets the controller and requires the controller to be reinitialized completely. Cycling power will also reset controller's fault condition. Reset is required when controller enters into a state that prevents it from continuing its operation unless it is completely recycled.
- **Reset Fault** – Resets a controller fault condition. A fault condition can occur when controller fails to execute an internal command. By

resetting the fault condition, the pump can proceed with the rest of its operation without any need to reinitialize or recycle the power on the controller.

Menu Items

Menu items located on top of the Configuration screen provide access to functionalities that are not directly related to the operation of the pump. The following sections will provide more detail on each of these menu items:

Configuration File – When selected, it displays two commands: **Save** and **Open**.

- **Save** - Allows the user to save current context of the FMI Configuration Tool. All Parameter settings that are on the current view will be stored into a file. User will be able to choose location and name of the file.
- **Open** – Allows the user to restore FMI Configuration Tool's context from a file created using the Save command. An error message will be displayed if contents of the file are not compatible with running the FMI Configuration Tool.

Settings – Provides access to “Turn TOP Most On” and “Turn Top Most Off”. By turning Top Most On, the FMI Configuration tool window becomes the top most window on the desktop.

Tools – Provides access to **Program** menu item. This option will make it possible to update the firmware in ICST02 controller. First, a window will be displayed to help locate the file (with “sw” extension) that will be uploaded into the controller. A prompt will be displayed if an attempt is made to upload an older version of the firmware into the controller. If user chooses to move forward with an upload, upload starts, and mouse cursor changes to an hour glass. The upload normally lasts around 30 seconds depending on the speed of the communication channel. Upon successful upload of the firmware, controller will be recycled (Reset) by the FMI Configuration Tool. The FMI Configuration tool will connect to the controller automatically after it is recycled. At this point controller should be running the newly uploaded firmware.

After a successful connection to the controller, its **model** and **App ID** (Application ID) will be retrieved by the FMI Configuration Tool. These values will be displayed at the upper left hand corner of the configuration screen.

Aside from Model and App ID, “**Flag Present?**” is displayed. Flag Present allows the user to enable/disable the sensor used to detect the flag. Display of

Fluid metering

Home and Park buttons in the Pump Control is managed by the value of Flag Present setting. If Flag Present is set to “No”, both Home and Park buttons will disappear.

By pressing “**Save selected parameters into controller**”, the configuration tool will attempt to save all the selected motion parameters into the controller. This way when controller is operated manually, values that are stored in the controller will be used to drive the pump.

To allow manual operation of the pump, while configuration tool is connected to the controller, you must uncheck “**Start/Stop using FMI Configuration Tool**” located at the lower right hand side of the screen (see *Figure 5*). When unchecked, all Pump Control elements on the user interface such as Start, Stop, and Park will be disabled, otherwise these elements will be enabled to allow control of the pump through the configuration tool.

If last set of values that were selected during operation of the pump were the ones displayed on the Analog Input column, user should be able to operate the pump using digital I/O lines provided on the ICST02 motherboard. To the same token, if last set of values that were used before unchecking “**Start/Stop using FMI Configuration Tool**”, the user can operate the pump using values stored in the controller (displayed on the controller column). In this mode of operation, the user can also adjust Flow Method and Flow Direction using their respective digital I/O lines.

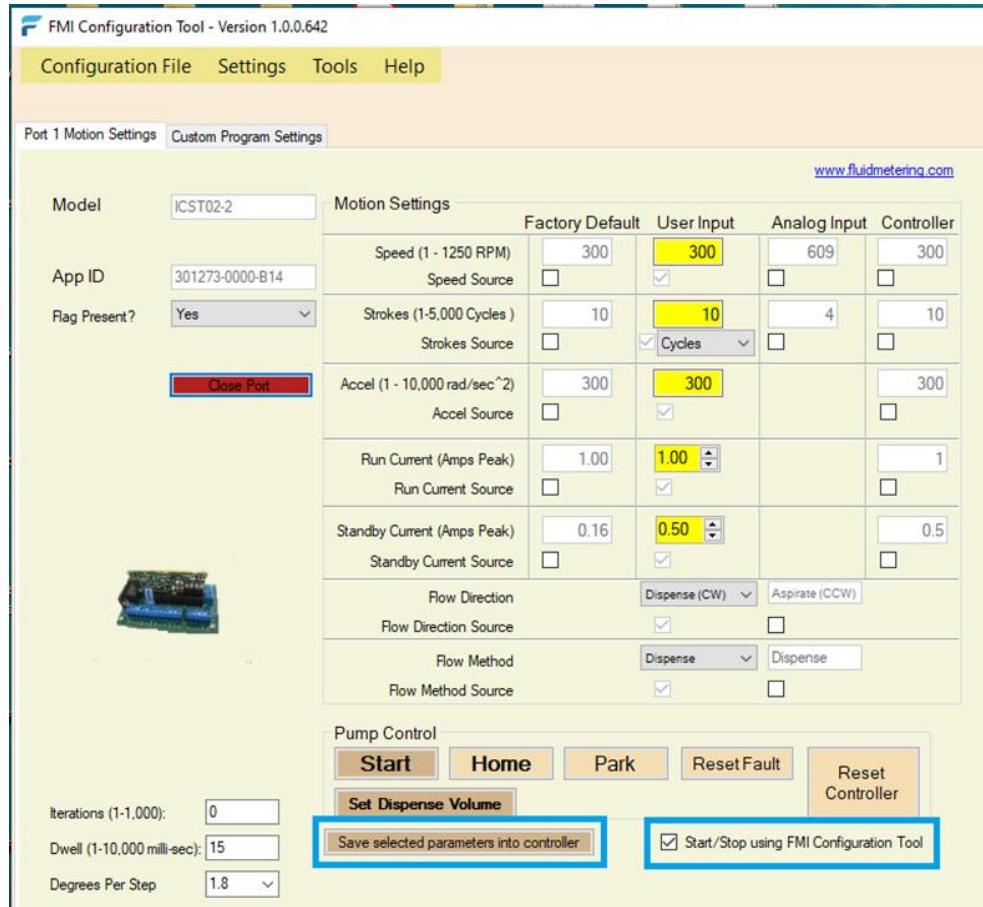

Figure 5 – Placing Controller in Manual Operation Mode

Custom Program Settings

Settings in this tab (See Figure 6) facilitate defining motion profiles using up to 16 phases of customized motor operations. This should assist in creating complex scenarios that may be required when operating an attached pump.

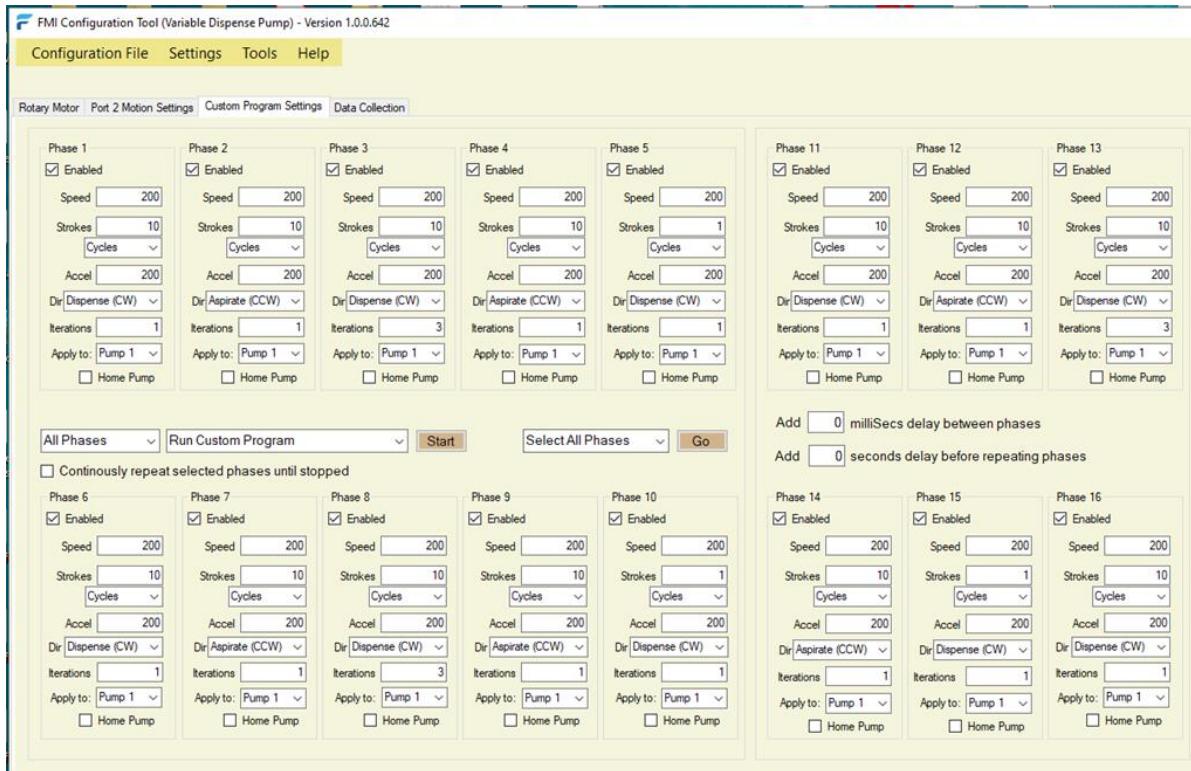

Figure 6 – Custom Program Settings

User can choose to operate a specific phase or all selected phases up to 16 phases of operation. In each phase user can define motion parameters of interest, and if the pump should be Homed before selected phase starts. Also, user is allowed to force all selected phases to cycle indefinitely until stopped, as well as, configure a delay period that takes effect before next cycle starts.

FMI Configuration Tool automatically restores all Custom Program Settings that was used in previous execution of the application. Using “Load Custom Settings Parameters” and “Save Custom Settings Parameters” (See Figure 7), Configured Program Settings can be stored and restored for future use.

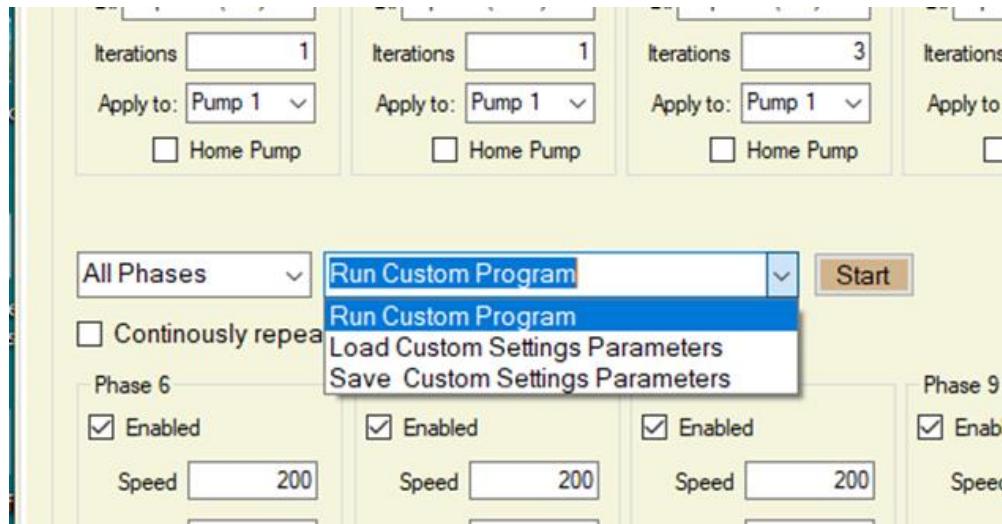

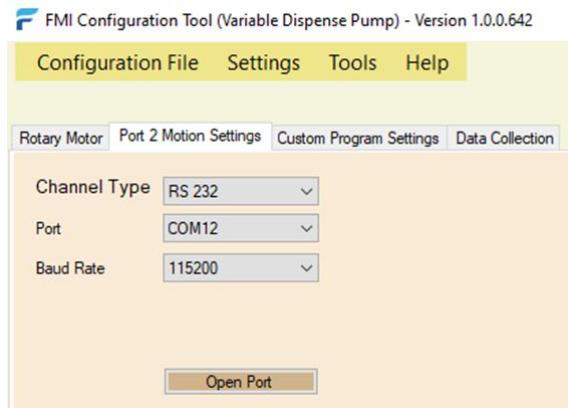

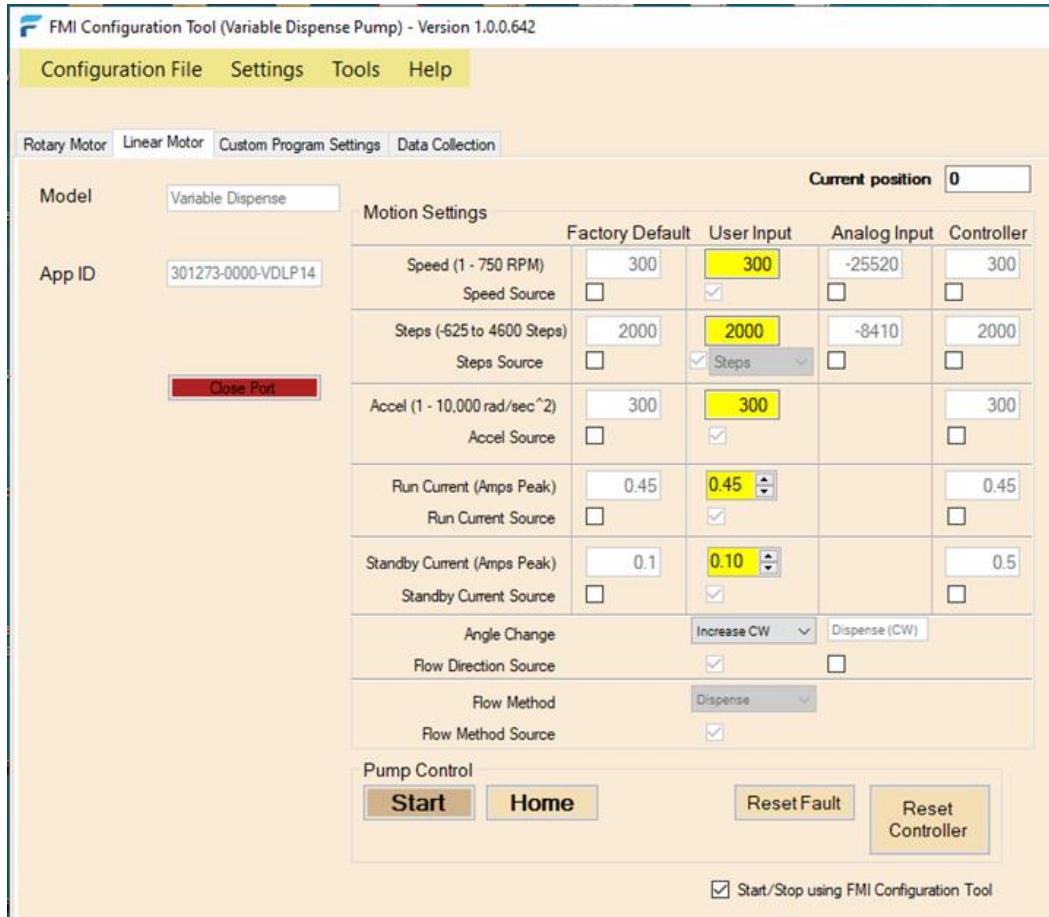

Figure 7 – Loading and Storing Custom Program Settings

Operating the Variable Dispense Actuator

If serial connection to rotary motor has already been opened, by switching to **Port 2 Motion Settings**, communication parameters necessary for connecting to linear pump's motor can be selected. Click on **Open Port** to connect to the Linear Pump's controller.

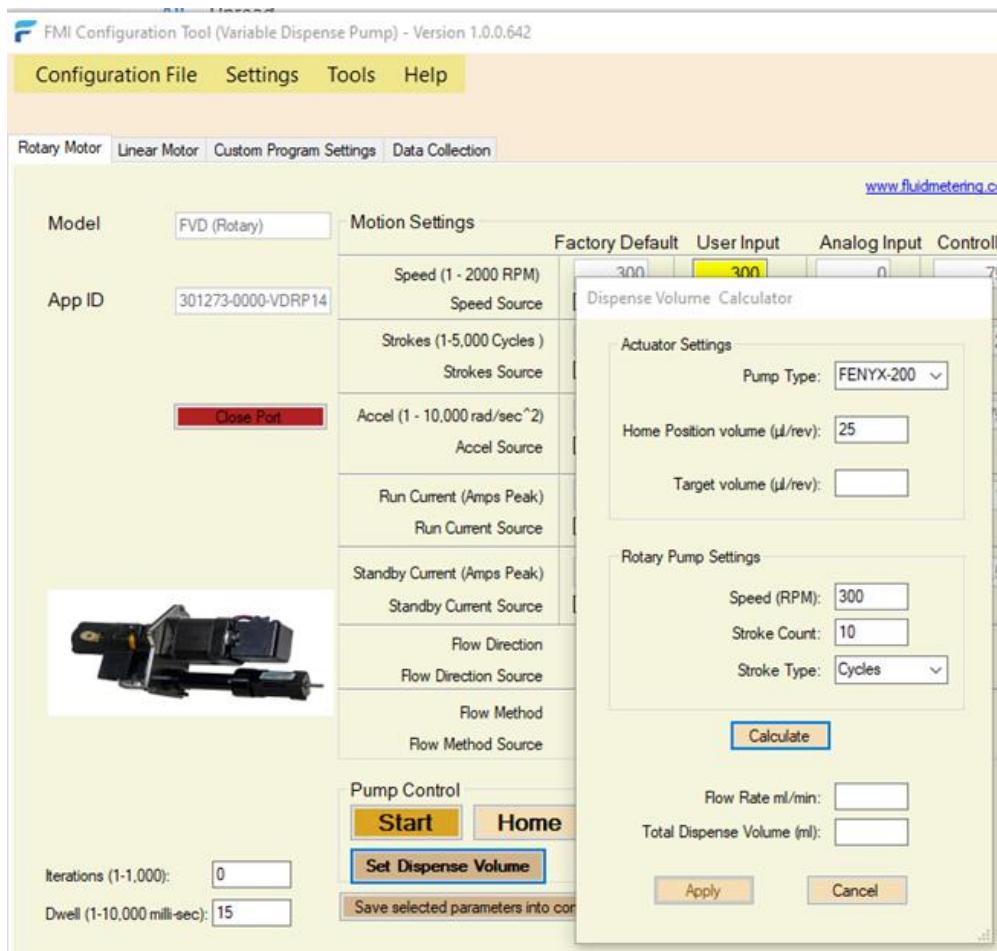

After successful connection, name of the tab will be changed to Linear Motor, and motion parameters that can be used to operate against the Linear Pump's motor will be displayed.

Instructions provided in section **Pump Control** can also be used to operate the Linear Motor. By adjusting the setting “**Angle Change**” motion parameter to **Increase**, the dispense angle of the actuator will increase that will result in higher flow rate. Conversely, to decrease the dispense angle of the linear actuator, set the “**Angle Change**” to **Decrease**. This will result in lower flow rate. FMI Configuration Tool will pop up a warning message if number of steps you try to adjust the actuator’s angle with violates the maximum (4600 steps) and minimum (-625 steps) limits.

Dispense Volume Calculator

Click on “**Set Dispense Volume**” to open the volume calculator. This calculator helps to figure out the angle that actuator has to be opened to achieve the flow rate on the rotary pump for configured rotary motor’s speed.

To start with you must position the actuator at its home position and force the rotary motor to move one full rotation. After measuring volume of fluid that is dispense, replace home position volume (default value of 25 $\mu\text{l}/\text{rev}$) with measured value. Next enter a value for the desired **Target volume**.

Next, adjust entries in **Rotary pump settings**. Click on Calculate. If calculated **Flow Rate** and **Total Dispense Volume** are satisfactory, click on **Apply**. At this point FMI Configuration tool automatically adjusts the actuator's angle and updates all motion parameter settings for the rotary pump. Clicking on Rotary Motor tab's Start should result in dispense of fluid with a volume close to what had been calculated by **Dispense Volume Calculator**. If resulting value is different (can be due variety of external factors including inner diameter of tubing) you can make necessary manual adjustments to angle of the actuator to achieve more acceptable results.

J10.1	IN0	DRY CONTACT START INPUT (METERING: CONNECT TO GROUND AND OPEN TO STOP – DISPENSE: MOMENTARILY CONNECT TO GROUND TO START)
J10.2	IN1	DIRECTION (CW - LEAVE DISCONNECTED; CCW - CONNECT TO GROUND)
J10.3	IN2	METERING/DISPENSE (METERING - LEAVE DISCONNECTED; DISPENSE - CONNECT TO GROUND)
J10.4	IN3/SEN	SENSOR OUTPUT (BLUE WIRE)
J10.5	Vdisp	0 - 5 VDC INPUT TO SET NUMBER OF DISPENSE CYCLES (1 TO 20 REVOLUTIONS)
J10.6	ANODE	SENSOR ANODE (RED WIRE)
J10.7	GND	SENSOR CATHODE (BLACK WIRE)
J10.8	+5 VDC	OUTPUT (250 mA MAX)
J10.9	Vref	0 - 5 VDC INPUT TO SET SPEED IN RPM (10.25 TO 2005 RPM)
J10.10	OUT0	MOTION COMPLETE ("0" = MOTION COMPLETE, "1" = MOTION NOT COMPLETE)
J10.11	OUT1	ERROR GENERAL DRIVE ERROR - ("0" = ERROR, "1" = NO ERROR)
J10.12	GND	GENERAL DIGITAL GROUND

NOTES:

1. DIRECTION BASED ON VIEW FACING PUMP HEAD SIDE.
